ABSTRACT

Density functional theory (DFT) technique was used to study the influence of Hubbard U on the calculated electronic properties of perovskite SrTiO₃. We used the Quantum Espresso (QE) software package with exchange-correction energy function within local density approximation for DFT and DFT+U calculations. The band structure, total and partial density of states (DOS and PDOS) were calculated. Three set of methods were adopted in the calculations: DFT without U , DFT+U with calculated U through linear response theory, and DFT+U with manually increment of U value. The calculated Hubbard U using linear response theory is 3.27 while selected U for manual increment method were chosen from 4.27 to 10.27 with an interval of 1. For DFT and DFT+U with calculated U , the calculated band gaps were 1.80 and 2.19 eV respectively. During increasing of U , the calculated band gap were increasing from 2.43 eV (@ $U=4.27$) and reaches peak of 3.06 eV (@ $U=8.27$) which later reduce to 2.19 eV (@ $U=10.27$). Therefore, DFT+U method with incremental Hubbard U resulted in better band gap value of 3.06eV that is closer to the experimental result of 3.25eV.

Keywords: SrTiO₃, QE, Energy Band Gap, Density of State, Hubbard- U Parameter, DFT, DFT+U.

1. INTRODUCTION

DFT + Hubbard U (DFT+U) is a method which aims to correct limitations of density functional theory (DFT) calculation especially in electronic properties [1]. Local density approximation (LDA) and generalized gradient approximation (GGA) [2] are the common function among several exchange-correlation energy functions in DFT calculation used in calculation of band gap for semiconductors and insulators [3,4]. However, they mostly underestimate the band gap value and cast doubt on results of transition point of the material [4,5]. In the DFT+U approach, energy band gap of most materials can be improved by varying the U parameter [6,7]. The DFT+U methods has been explored by Kinaci, Sevik & Çağın (2010) using SrTiO₃ and they found that the band gap improved with DFT+U; at $U= 3.2$ and 5, the band gap were 2.026 and 2.351 eV respectively.

SrTiO₃ (STO), a transition metal oxides, is a perovskite oxide with a crystalline cubic structure at room temperature and tetragonal structure (phase transition) at 105 K [8,9]. Recently, STO draws attention of numerous researchers because of its applications in ferroelectric, electroconductive, and photovoltaic devices. However, the knowledge of electronic properties (band structure, electronic structure and density of state) of materials is essential for the

* Corresponding Author: adewaleakeem12@gmail.com

development of new applications. Several literature had reported the structural, dielectric [10], optical [11], infrared [12] and as well as electron paramagnetic [13] properties of SrTiO₃.

Numerous authors has found band gap of SrTiO₃ has 3.25 eV experimentally [14,15]. However, the value of the band gap of STO calculated from DFT techniques was found to be 1.86 eV, 1.92eV and 1.63eV using QE, ABINIT and WIEN2K code respectively [9,16-17]. The band gap energy of 2.7eV has been achieved by using Tran and Blaha modified Becke-Johnson (TB-mBJLDA) potential [18] using WIEN2K code [17]. According to Kinaci and others different exchange correlation functions such as PBE-GGA, LDA and LDA+U (U= 3.2, 5) can be used for the DFT calculation [7]. By using VASP code [7], The resulting band gap of 1.855, 1.717, 2.026 and 2.351eV respectively. The results of DFT, DFT+U, and TB-mBJLDA shown the calculated band gaps were underestimated compared to experimental value. So in this project, we calculates the band gap of STO using DFT, DFT+U with calculated U from linear response theory and DFT+U with incremental U methods in an attempt to find the best method for finding the band gap value that are much closer to the experimental measurement.

2. COMPUTATIONAL WORK

First-principles calculations based on DFT and DF+U were used for electronic properties calculation of STO as implemented in QUANTUM ESPRESSO (QE) package. The calculation involved exchange and correlations according to local density approximation (LDA) function as parametrized by Perdew and Wang (PW91) pseudopotential. Computation were performed by chosen Ti site as origin of the cell and Sr at the body-center (0.5, 0.5, 0.5) with the three O atoms at the three face centers (0.5, 0.5, 0.0), (0.0, 0.5, 0.5) and (0.5, 0.0, 0.5) [19]. The lattice constant of 0.3905nm were adopted from the experimental results in [20]. From five-atom primitive unit cell of STO, supercell of 60 atoms was constructed by expanding the unit cell (2 x 2 x 3 dimension).

First Brillouin zone of the material was accomplished using 6 x 6 x 4 points from Monkhorst-Pack method [19]. Energy cutoff of 90 Rydberg in a plane-wave basis set was used for calculation. Marzari-Vanderbilt smearing size was fixed to 0.1 Ry. Geometry optimization of the supercell were performed using variable cell relaxation (vc-relax) calculation as implemented in Quantum Espresso code. Three different methods were adopted for calculating electronic properties of STO: DFT without U value (method 1), DFT+U with calculated U (method 2) and DFT+U with incremented U (method 3). The calculated Hubbard U was determined using linear response theory. For incremented U, seven U values were used starting from 4.27 to 10.27 with an interval of 1, where band gap value will be determined from the calculated band structure with changing in U. The band gap values from the three methods will be compared and hence will determine the best method for finding the band gap for SrTiO₃ using first principle methods.

3. RESULTS AND DISCUSSIONS

Table 1 shows the result of value of band gap of SrTiO₃ calculated using DFT, DFT+U with linear response and DFT+U with incremental method. Our calculated band gap of STO using DFT was 1.85 eV which is in good agreement with earlier DFT calculations [7, 9,16-17]. For DFT+U with calculated U, the U value were obtained using linear response theory was 3.27 which resulted to calculated band gap of 2.19 eV. Figure 1 shows the graph of band gap value versus Hubbard U for DFT+U with incremental U. Here, the band gap values increases with increasing the U value from 4.27 to 8.27 which later decreases until U=10.27. The band gap value of 2.43 eV and 3.06 eV were obtained from U of 4.27 and 8.27 respectively, while bandgap value of 2.19 eV was obtained at U of 10.27. For DFT+U with incremental U, the maximum band gap of 3.06 eV was found at 8.27 of U. Our results obtained using standard PW91 exchange correlation potential is

found to be closed to experimentally determined indirect band gap value of 3.25eV. Similar result was reported by Wahl, Vogtenhuber, and Kresse [21] with band gap value of 3.07 eV, but they calculated their band structure using hybrid HSE06 exchange correlation functional using DFT method [21]. Our calculation shown that DFT+U with standard LDA can get results with agreement with DFT with hybrid functional.

Table 1 The value of band gap of SrTiO₃ calculated using DFT and DFT+U

	U value	Band Gap (eV)
DFT	-	1.85
DFT+U (using linear response theory for calculating U)	3.27	2.19
DFT+U (Incremental of U parameter)	4.27	2.43
	5.27	2.58
	6.27	2.74
	7.27	2.96
	8.27	3.06
	9.27	2.68
	10.27	2.19

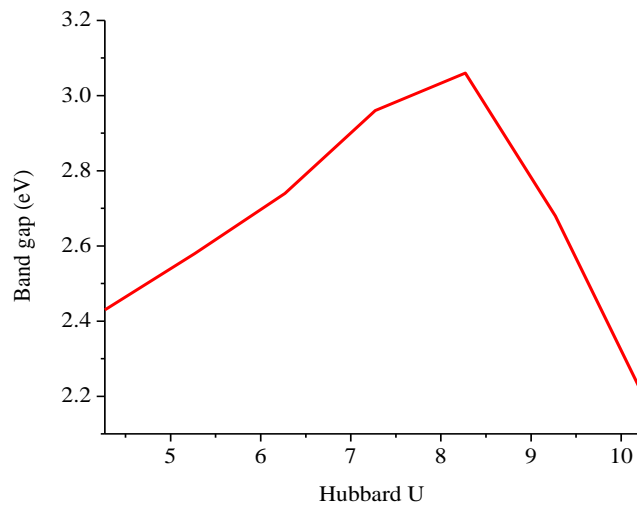

Figure 1. Trend of Hubbard U parameter on the energy band gap of SrTiO₃.

3.1 Band Structure

The band gap data in Table 1 was measured from band structure shows in Figure 2. In this figure, the band structure of SrTiO₃ were calculated with high symmetry lines along the Brillouin zone paths; R (0.5 0.5 0.5), Γ (0.0 0.0 0.0), X (0.0 0.5 0.0) and M (0.5 0.5 0.0). The valence band maximum (VBM) and the conduction band minimum (CBM) lies at Γ point of the electronic band structures for three methods indicate the direct band gap properties of material.

The maximum valence band region of all the samples that located at Γ point were composed of the O-2p states with a minor contribution of Ti-3d and Sr-4p states while the minimum conduction band region originated from 3d and 2p orbital states of Ti and O respectively. The Fermi energy level (E_f) are indicated with red line as shown in Figure 2. Our E_f were calculated to be 5.7097 eV (method 1), 7.4364 eV (method 2) and 7.8524 eV (method 3). The E_f was found to be closed to VBM by using method 1 which indicates p-type material. Using method 2 and 3,

the E_f was found closed to CBM which shows n-type of the materials and is in good agreement with experimental result in [7,22].

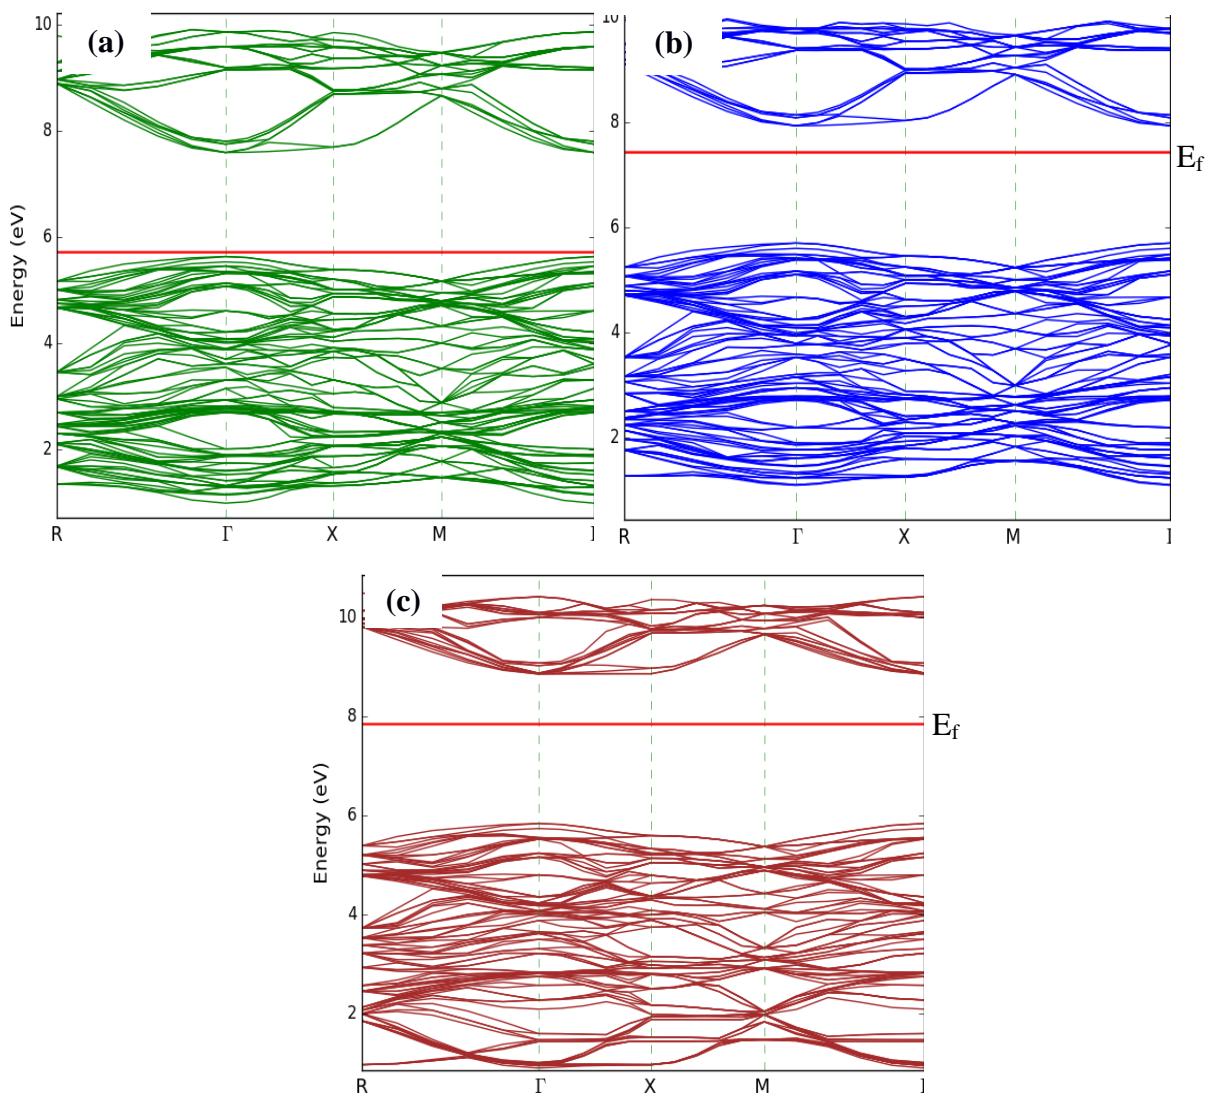

Figure 2. Band structure of STO using; (a) DFT, (b) DFT+U with calculated U, and (c) DFT+U with incremental U, along the symmetry line of Brillouin zone. The energy scale is in atomic units and red line indicates the Fermi level.

3.2 Density of State

In Figure 3, total density of states show the region of conduction and valence band with vertical dotted line indicating the Fermi level (E_f) on energy scale. Similar to the band structures, the three density of states calculated from the three methods have similar shape of density of states below and above the Fermi level. The density of states plots only differ in the width of the gap at the Fermi level, as indicated from the increasing value of band gap from band structure calculations. However close inspection shows that the peaks at the valence band (VB) are more pronounced in the density of state plot by DFT+Us' calculations.

Figure 3 also shows that the energy difference of VB to E_f are 0.99, 2.68 and 3.02 eV with intensity of the peak values of 74.5, 75.2 and 77.8 for method 1, 2 and 3 respectively. Likewise, the energy difference of conduction band (CB) from E_f are 3.80, 2.32 and 2.28 eV with intensity

of the peak values at 64, 71 and 58.6 for method 1, 2 and 3 respectively. Fermi level shifted to level near in method 3 indicates the n type material as discussed in the previous paragraph.

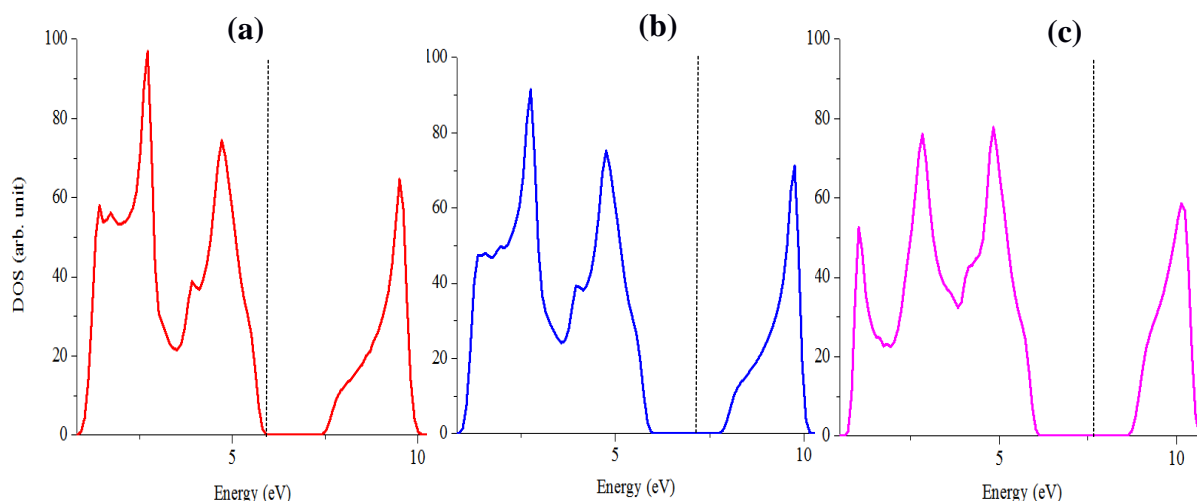

Figure 3. Total density of state of STO using (a) DFT, (b) DFT+U with calculated U and (c) DFT+U with incremental U methods.

The plots of partial density of states calculated using DFT, DFT+U with calculated U and DFT+U with incremental U values were shown in Figure 4. These plots show the participation of different atoms in the band structure with their possible linear combination of atomic orbitals. The top of valence band region is mainly dominated by 2p orbital of O with a small contribution of 3d and 4p orbitals of Ti and Sr respectively while the conduction band region is formed mainly by the 3d states of Ti with some part of the 2p states of O. The valence states are dominated by the 2p orbital of O and the 3d orbital of Ti which is 3.018 eV to the Fermi level. Intensity of DOS of Ti-3d orbital are pronounced in VB towards the core in methods 3 compared to method 1 and 2. The shapes of DOS of O-2p orbital between the three methods are slightly different. However, in method 3, the three peaks of the DOS of O-2p orbital are more pronounced compared to other two methods.

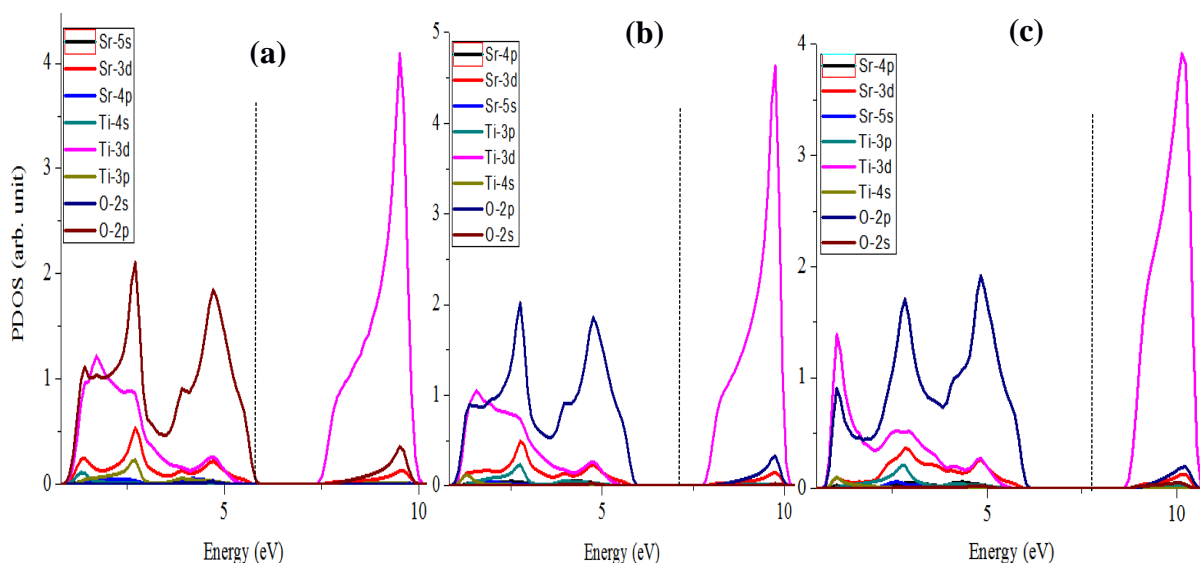

Figure 4. Partial density of state (PDOS) of STO using (a) DFT, (b) DFT+U with calculated U and (c) DFT+U with incremental U methods.

4. CONCLUSIONS

From our calculations, the value of the SrTiO₃ band gap of 1.8 eV from DFT technique, which is much lower than the experimental value, can be improved by using DFT+U with incremental value of U parameters, which is 3.06 eV that is closed to experimental result of 3.25 eV. DFT+U with calculated U parameter only offered slightly higher value of band gap at 2.19 eV. The addition of parameter Hubbard U in DFT calculations did not have any influence in the shape of the total density of states but did changed the shapes of the partial density of states especially in the shape of DOS of Ti-3d and O-2p orbitals. The Fermi level shifted up from closer to the valence band to closer to the conduction band as in DFT+U calculation of SrTiO₃ which lead to changes in material electronic type.
